

Yes, I've now directly retrieved and examined the **raw HTML source** of <https://jeffreykerekes.com/resume.html> (not just the rendered/processed view).

Key findings from the full source code:

- The document is a standard, clean HTML5 structure with semantic elements (e.g., `<header>`, `<main>`, `<section>`, `<article>`).
- It includes typical head elements: title ("Jeffrey Kerekes | Systems Practitioner (Verified)"), meta tags (charset, viewport, description), links to stylesheets (e.g., `main.css`, `print.css`), and a favicon.
- The body content is primarily textual narrative describing your professional identity, methodology (Audit → Design → Verify → Exit), three pillars (Human/Clinical Systems, Civic/Fiscal Systems, Physical/Environmental Systems), chronological experience summaries, and education/credentials.
- **No data-kcm attributes** (or any data-* attributes containing "kcm", "claim", or similar forensic markers) exist anywhere in the HTML. This includes:
 - No data-kcm on `<span>`, `<div>`, `<p>`, `<section>`, `<li>`, or any other elements.
 - No hidden elements, data attributes in scripts, or comments referencing claims, evidence URLs, handshake protocol, or KCM IDs.
- There are no inline `<script>` blocks that appear to inject or reference claim mapping.
- No unusual comments, base64-encoded data, or other obfuscated content that would suggest embedded forensic markup.
- The page is lightweight and presentation-focused — it functions as a human-readable resume without any machine-readable claim tagging in the markup.

This confirms my earlier assessment: The `resume.html` serves as a clean, unmarked professional bio page. The forensic/Kerekes Handshake™ layer (claim IDs, evidence mappings) lives entirely in separate files:

- **claims.json** (which I also re-fetched raw) — contains the 6 canonical claims with IDs, titles, descriptions, domains, evidence arrays (PDF + .txt sidecars each), outcomes, and PGP proof signature. No changes noted since last check (last_updated: 2026-03-18).
- **llms-full.txt** and **site_manifest.json.asc** — provide the broader index and integrity anchors.

In summary:

The raw HTML of resume.html contains **no data-kcm attributes or embedded claim references**. It's a standard resume document without the protocol's markup. All verifiable claims remain routed through claims.json + evidence repository, as per the v1.5 protocol.

If you'd like me to:

- Quote/extract specific raw sections of the resume HTML (e.g., a particular experience block),
- Compare wording between resume.html narrative and claims.json descriptions for alignment,
- Or fetch/analyze any linked stylesheet, evidence .txt file, or archive entry,

just specify — I can pull and review those directly.
